# THE EFFECT OF BIOGAS SLURRY <br> ON YIELD AND QUALITY OF OATS AND FESCUE PLANTED IN MACUBENI, EASTERN CAPE, SOUTH AFRICA 

N Matyholo - Mapeyi and
J Gambiza

Province of the
EASTERN CAPE

RHODES UNIVERSITY
Wbere leaders learn

## INTRODUCTION

- The low quantity and poor quality of forage in rangelands- the dry season is one of the major factors limiting livestock production in the smallholder sector.
- The growing of fodder species and use of inorganic fertilizer is a commonly used strategy to increase fodder quantity, BUT BIOSLURRY-organic

## OBJECTIVES

- To study the effect of biogas slurry on quality of oats and fescue
- To study the effect of biogas slurry on quantity of oats and fescue
- To introduce a new cost effective source of bioenergy that is environmentally friendly to the ecosystem in rural community

## MATERIALS AND METHODS

- Study site
- Macubeni in Lady Frere in the Eastern Cape
- 40 km south west of Indwe and 20 km north of Lady Frere - Malahleni local municipality in the Chris Hani district municipality $27^{\circ} 01-16^{\prime} E$ and $31^{\circ}$ 27-36' S
- The average rainfall is $501-600 \mathrm{~mm}$ per annum
- The soil types of the selected sites are a mosaic of mudstones and sandstones with dolerite intrusions (Shackleton and Gambiza, 2008)
- The soils are stony and shallow

## METHODOLOGY

- Annual legume and grass (ALG) were arrow leaf clover, Trifolium vesiculosum and oats, Avena sativa species that were grown together per treatment. Perennial legume and grass (PLG)-were white clover, Trifolium repense and fescue, Arundicenae festuca grown together in a treatment. In 2012 and 2013 slurry was applied to treatment/plots seven weeks after planting and then fortnightly thereafter until the third cut on the soil surface between forage

## METHODOLOGY CONT.

- Twenty litres of water were applied to no slurry treatments
- Slurry was applied once and incorporated into the soil in 2014 and slurry treatments (PLGs and ALGs) were irrigated; the zero slurry applied (PLGo and ALGo) were not irrigated. Treatments were applied in a factorial design with three replicates
- Forage was harvested - $1 \mathrm{~m}^{2}$ quadrat in the centre of each treatment
- Forage was cut three times per year in May (cut 1), July (cut 2) and September (cut 3) each year

## RESULTS AND DISCUSSION

Table showing 2012 average DMY per treatment (kg/ha)

$$

## CONCLUSION AND REMARKS

- DMY significant differences-2012
- 2013/14 -dry
- Irrigation was not enough
- Legumes were impossible to measureperformance
- Scorching vs limiting moisture
- Site differences in DMY

## CONCLUSION AND REMARKS CONT.

- Non slurry treatments outperformed slurry applied-perennial and annual sp.
- Less N than required
- Measuring slurry N each year
- Dry and cold winter
- Follow up trial on different levels of slurry N
- Labour intensive, but cost effective
- Site differences in yield were due individual participant management and exposure to wild vermin and chickens (enclosure cages)

## Thank You
